---

---

## Routing: What is it?

- Process of finding a path from a source to every destination in the network
- Suppose you want to connect to Antarctica from your desktop
  - what route should you take?
  - does a shorter route exist?
  - what if a link along the route goes down?
  - what if you're on a mobile wireless link?
- Routing deals with these types of issues

locigno@disi.unitn.it

4

---

---

---

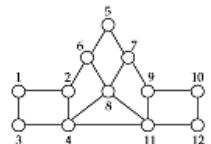

---

---

---

## Basics

- A routing protocol sets up a **routing table** in routers
  - internal table that says, for each destination, which is the next output to take
- A node makes a local choice depending on global topology: this is the fundamental problem

ROUTING TABLE AT 1

Destination	Next hop	Destination	Next hop
1	—	7	2
2	2	8	2
3	3	9	2
4	3	10	2
5	2	11	3
6	2	12	3

locigno@disi.unitn.it

5

---

---

---

---

---

---

## Key problem

- How to make correct local decisions?
  - each router must know something about global state
- Global state
  - inherently large
  - dynamic
  - hard to collect
- A routing protocol must intelligently summarize relevant information

locigno@disi.unitn.it

6

---

---

---

---

---

---

## Requirements

- Minimize routing table space
  - fast to look up
  - less to exchange
- Minimize number and frequency of control messages
- Robustness: avoid
  - black holes
  - loops
  - oscillations
- Use optimal path

locigno@disi.unitn.it

7

## Different degrees of freedom

- Centralized vs. distributed routing
  - centralized is simpler, but prone to failure and congestion
- Global vs local information exchange
  - convey global information is expensive
- Static vs dynamic
  - static may work at the edge, not in the core
- Stochastic vs. deterministic
  - stochastic spreads load, avoiding oscillations, but misorders
- Single vs. multiple path
  - primary and alternative paths (compare with stochastic)
- State-dependent vs. state-independent
  - do routes depend on current network state (e.g. delay)

locigno@disi.unitn.it

8

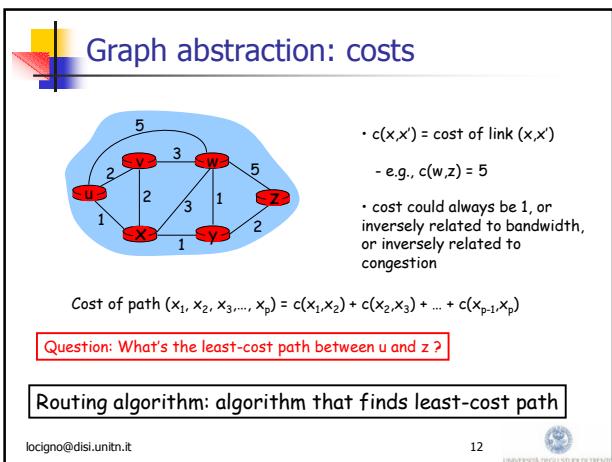

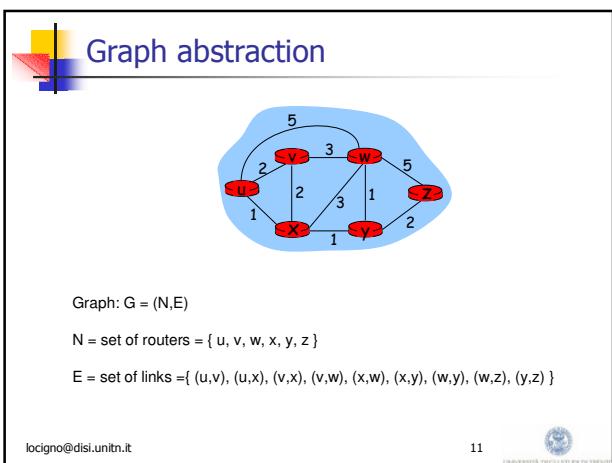

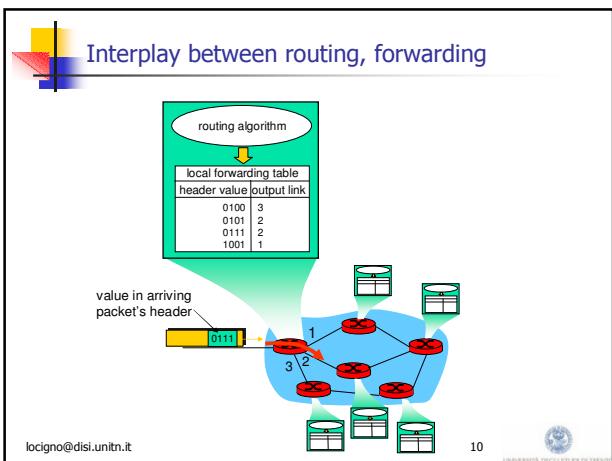

## Dynamic Routing And Routers

- To ensure that all routers maintain information about how to reach each possible destination
  - each router uses a **route propagation protocol**
    - to exchange information with other routers
    - when it learns about changes in routes
    - updates the local routing table
- Because routers exchange information periodically
  - the local routing table is updated continuously

locigno@disi.unitn.it

9

## Distance Vector Algorithms

---

---

---

---

---

---

### Consistency criterion

Define

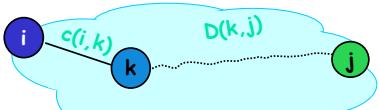

$c(i,k)$  := cost from  $i$  to  $k$  (direct connection)

$D(i,j)$  := cost of least-cost path from  $i$  to  $j$

→ The subset of a shortest path is also the shortest path between the two intermediate nodes

- Then, if the shortest path from node  $i$  to node  $j$ , with distance  $D(i,j)$ , passes through neighbor  $k$ , with link cost  $c(i,k)$ , we have:

$$\bullet D(i,j) = c(i,k) + D(k,j)$$

locigno@disi.unitn.it

14

---

---

---

---

---

---

### Distance Vector (DV) algorithm

- Initial distance values (iteration 1):
  - $D(i,i) = 0$  ;
  - $D(i,k) = c(i,k)$  if  $k$  is a neighbor (i.e.  $k$  is one-hop away); and
  - $D(i,j) = \text{INFINITY}$  for all other non-neighbors  $j$ .
- Note that the set of values  $D(i,*)$  is a distance vector at node  $i$ .
- The algorithm also maintains a next-hop value (forwarding table) for every destination  $j$ , initialized as:
  - $\text{next-hop}(i) = i$ ;
  - $\text{next-hop}(k) = k$  if  $k$  is a neighbor, and
  - $\text{next-hop}(j) = \text{UNKNOWN}$  if  $j$  is a non-neighbor.

locigno@disi.unitn.it

15

---

---

---

---

---

---

## Distance Vector (DV) algorithm

- After every iteration each node  $i$  exchanges its distance vectors  $D(i,*)$  with its immediate neighbors.
- For any neighbor  $k$ , if  $c(i,k) + D(k,j) < D(i,j)$ , then:
  - $D(i,j) = c(i,k) + D(k,j)$
  - $\text{next-hop}(j) = k$

locigno@disi.unitn.it

16   
UNIVERSITÀ DEL TRENTO

## In summary

Basic idea:

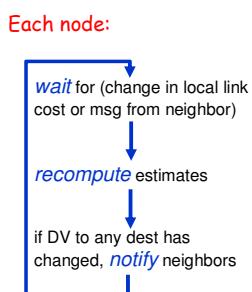

- From time-to-time, each node sends its own distance vector estimate to neighbors
- Asynchronous
  - When a node  $x$  receives new DV estimate from neighbor, it updates its own DV using B-F equation:  
$$D(x,y) \leftarrow \min_v \{c(x,v) + D(v,y)\} \quad \text{for each node } y \in N$$
  - Under minor, natural conditions, the estimate  $D(x,y)$  converges to the actual least cost

locigno@disi.unitn.it

17   
UNIVERSITÀ DEL TRENTO

## In summary

- Iterative, asynchronous:  
each local iteration caused by:
  - local link cost change
  - DV update message from neighbor
- Distributed:  
each node notifies neighbors only when its DV changes
  - neighbors then notify their neighbors if necessary

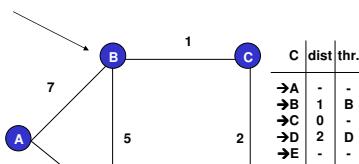

locigno@disi.unitn.it

Router D		
Dest	Next	Metric
NTW_1	dir	1
NTW_1		

26

locigno@disi.unitn.it

27

## Solution to “counting to infinity”

- Maximum number of hops bounded to 15
  - this limits the convergence time
- Split Horizon
  - simple
    - each node *omits* routes learned from one neighbor in update sent to that neighbor
  - with poisoned reverse
    - each node *include* routes learned from one neighbor in update sent to that neighbor, setting their metrics to infinity
    - drawback: routing message size greater than simple Split Horizon

locigno@disi.unitn.it

28

---

---

---

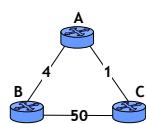

---

---

---

## Distance Vector: link cost changes

- If link cost changes:
  - good news travels fast
    - good = cost decreases
  - bad news travels slow
    - bad = cost increases
- Exercise
  - try to apply the algorithm in the simple scenario depicted above when
    - the cost of the link A → B changes from 4 to 1
    - the cost of the link A → B changes from 4 to 60

locigno@disi.unitn.it

29

---

---

---

---

---

---

## RIP at a glance

- Routing IInformation PProtocol
- A simple intradomain protocol
- Straightforward implementation of Distance Vector Routing...
  - Distributed version of Bellman-Ford (DBF)
- ...with well known issues
  - slow convergence
  - works with limited network size
- Strengths
  - simple to implement
  - simple management
  - widespread use

locigno@disi.unitn.it

30

---

---

---

---

---

---

## RIP at a glance

- Metric based on hop count
  - maximum hop count is 15, with "16" equal to " $\infty$ "
  - imposed to limit the convergence time
  - the network administrator can also assign values higher than 1 to a single hop
- Each router advertises its distance vector every 30 seconds (or whenever its routing table changes) to all of its neighbors
  - RIP uses UDP, port 520, for sending messages
- Changes are propagated across network
- Routes are timeout (set to 16) after 3 minutes if they are not updated

locigno@disi.unitn.it

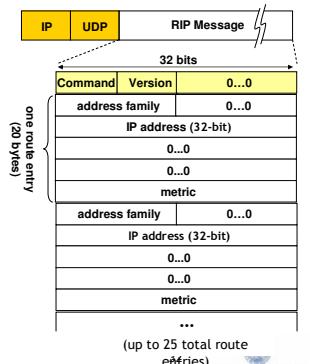

31

## RIP: Message Format

- Command: 1=request 2=response
  - Updates are replies whether asked for or not
  - Initializing node broadcasts request
  - Requests are replied to immediately
- Version: 1
- Address family: 2 for IP
- IP address: non-zero network portion, zero host portion
  - Identifies particular network
- Metric
  - Path distance from this router to network
  - Typically 1, so metric is hop count

locigno@disi.unitn.it

## RIP procedures: introduction

- RIP routing tables are managed by application-level process
  - e.g., *routed* on UNIX machines
- Advertisements are sent in UDP packets (port 520)
- RIP maintains 3 different timers to support its operations
  - Periodic update timer (25-30 sec)
    - used to sent out update messages
  - Invalid timer (180 sec)
    - If update for a particular entry is not received for 180 sec, route is invalidated
  - Garbage collection timer (120 sec)
    - An invalid route is marked, not immediately deleted
    - For next 120 s, the router advertises this route with distance infinity

locigno@disi.unitn.it

33

## RIP procedures: input processing

- Request Messages
  - they may arrive from routers which have just come up
  - action: the router responds directly to the requestor's address and port
    - request is processed entry by entry
- Response Messages
  - they may arrive from routers that perform regular updates, triggered updates or respond to a specific query
  - action: the router updates its routing table
    - in case of new route or changed routes, the router starts a triggered update procedure

locigno@disi.unin.it

34

---

---

---

---

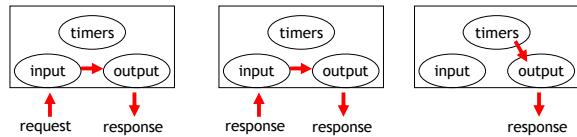

---

---

## RIP procedures: output processing

- Output are generated
  - when the router comes up in the network
  - if required by the input processing procedures
  - by regular routing update
- Action: the router generates the messages according to the commands received
  - the messages contain entries from the routing table

locigno@disi.unin.it

35

---

---

---

---

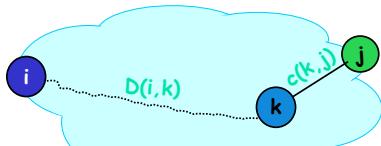

---

---

## Link State (LS) Approach

- The link state (Dijkstra) approach is iterative, but it pivots around destinations  $j$ , and their predecessors  $k = p(j)$ 
  - Observe that an alternative version of the consistency condition holds for this case:  $D(i,j) = D(i,k) + c(k,j)$

- Each node  $i$  collects all link states  $c(*,*)$  first and runs the complete Dijkstra algorithm locally.

locigno@disi.unin.it

36

---

---

---

---

---

---

## Link State (LS) Approach...

- After each iteration, the algorithm finds a new destination node  $j$  and a shortest path to it.
- After  $m$  iterations the algorithm has explored paths, which are  $m$  hops or smaller from node  $i$ .
  - It has an  $m$ -hop view of the network just like the distance-vector approach
- The Dijkstra algorithm at node  $i$  maintains two sets:
  - set  $N$  that contains nodes to which the shortest paths have been found so far, and
  - set  $M$  that contains all other nodes.
- For all nodes  $k$ , two values are maintained:
  - $D(i,k)$ : current value of distance from  $i$  to  $k$ .
  - $p(k)$ : the predecessor node to  $k$  on the shortest known path from  $i$

locigno@disi.unitn.it

37

## Dijkstra: Initialization

- Initialization:
  - $D(i,i) = 0$  and  $p(i) = i$
  - $D(i,k) = \infty$  and  $p(k) = i$  if  $k$  is a neighbor of  $i$
  - $D(i,k) = \infty$  and  $p(k) = \text{UNKNOWN}$  if  $k$  is not a neighbor of  $i$
  - Set  $N = \{i\}$ , and next-hop ( $i$ ) =  $I$
  - Set  $M = \{j \mid j \neq i\}$
- Initially set  $N$  has only the node  $i$  and set  $M$  has the rest of the nodes.
- At the end of the algorithm, the set  $N$  contains all the nodes, and set  $M$  is empty

locigno@disi.unitn.it

38

## Dijkstra: Iteration

- In each iteration, a new node  $j$  is moved from set  $M$  into the set  $N$ .
  - Node  $j$  has the minimum distance among all current nodes in  $M$ , i.e.  $D(i,j) = \min \{l \in M\} D(i,l)$ .
  - If multiple nodes have the same minimum distance, any one of them is chosen as  $j$ .
  - Next-hop( $j$ ) = the neighbor of  $i$  on the shortest path
    - Next-hop( $j$ ) = next-hop( $p(j)$ ) if  $p(j) \neq i$
    - Next-hop( $j$ ) =  $j$  if  $p(j) = i$
  - Now, in addition, the distance values of any neighbor  $k$  of  $j$  in set  $M$  is reset as:
    - If  $D(i,k) < D(i,j) + c(j,k)$ , then  
 $D(i,k) = D(i,j) + c(j,k)$ , and  $p(k) = j$ .
- This operation is called "relaxing" the edges of node  $j$ .

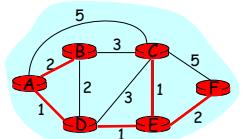

locigno@disi.unitn.it

39

## Dijkstra's algorithm: *example*

Step	set N	D(B),p(B)	D(C),p(C)	D(D),p(D)	D(E),p(E)	D(F),p(F)
0	A	2,A	5,A	1,A	infinity	infinity
1	AD	2,A	4,D		2,D	infinity
2	ADE	2,A	3,E			4,E
3	ADEB		3,E			4,E
4	ADEBC					4,E
5	ADEBCF					

The shortest-paths spanning tree rooted at A is called an SPF-tree

locigno@disi.unitn.it

40

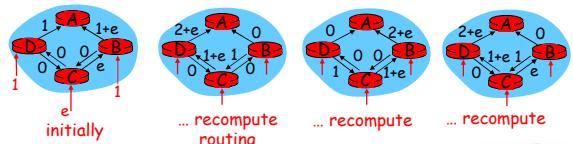

## Dijkstra's algorithm, discussion

## Algorithm complexity: n nodes

- each iteration: need to check all nodes,  $w$ , not in  $N$
  - $n(n+1)/2$  comparisons:  $O(n^2)$
  - more efficient implementations possible:  $O(n \log n)$

### Oscillations possible:

- e.g., link cost = amount of carried traffic

locigno@disi.unitn.it

41

## Summary: Distributed Routing Techniques

## Link State

- Topology information is flooded within the routing domain
  - Best end-to-end paths are computed locally at each router.
  - Best end-to-end paths determine next-hops.
  - Based on minimizing some notion of distance
  - Works only if policy is shared and uniform
  - Examples: OSPF  
  - Each router knows little about network topology
  - Only best next-hops are chosen by each router for each destination network.
  - Best end-to-end paths result from composition of all next-hop choices
  - Does not require any notion of distance
  - Does not require uniform policies

## Vectoring

- Each router knows little about network topology
  - Only best next-hops are chosen by each router for each destination network.
  - Best end-to-end paths result from composition of all next-hop choices
  - Does not require any notion of distance
  - Does not require uniform policies at all routers
  - Examples: RIP

locigno@disi.unitn.it

42

## Comparison of LS and DV algorithms

### Message complexity

- LS: with  $n$  nodes,  $E$  links,  $O(nE)$  msgs sent
  - DV: exchange between neighbors only
    - convergence time varies
- Speed of Convergence
- LS:  $O(n^2)$  algorithm requires  $O(nE)$  msgs
    - may have oscillations
  - DV: convergence time varies
    - may be routing loops
    - count-to-infinity problem

### Robustness: what happens if router malfunctions?

- LS:
  - node can advertise incorrect link cost
  - each node computes only its own table
- DV:
  - DV node can advertise incorrect path cost
  - each node's table used by others
    - error propagate thru network

locigno@disi.unitn.it

43

## Open Shortest Path First

- Nel 1988 IETF ha avviato la standardizzazione di un nuovo protocollo di routing
- IETF ha elencato in fase di avvio della standardizzazione un insieme di requisiti che il nuovo protocollo avrebbe dovuto rispettare:
  - soluzione NON proprietaria – aperta
  - parametri di distanza multipli
  - algoritmo dinamico
  - routing basato su *Type of Service*
  - *load balancing*
  - supporto di sistemi gerarchici
  - funzionalità di sicurezza
- Open Shortest Path First (1990, RFC 1247)

locigno@disi.unitn.it

44

## Criteri di progettazione

- I tre principali criteri di progettazione del protocollo OSPF sono:
  - distinzione tra host e router
  - reti broadcast
  - suddivisione delle reti di grandi dimensioni

locigno@disi.unitn.it

45

## Distinzione host/router (1)

- Nelle reti IP generalmente gli host sono collocati nelle aree periferiche della rete a sottoreti locali connesse alla Big Internet attraverso router
- Il modello link state prevede che il database *link state* includa una entry per ogni link tra host e router
- OSPF introduce il concetto di link ad una *stub network*
  - il link viene identificato dall'indirizzo della sottorete

locigno@disi.unitn.it

46

---

---

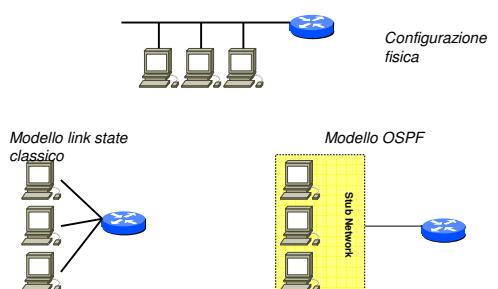

---

---

---

---

## Distinzione host/router (2)

locigno@disi.unitn.it

47

---

---

---

---

---

---

## Type of Service

- Per ogni link nel database link state possono essere memorizzate più metriche
  - Type of Service Metrics
- Al momento di aggiornamento delle tabelle di routing vengono distribuite tutte le metriche presenti per ogni link
- Il calcolo del percorso ottimo viene fatto
  - sempre per quanto riguarda la metrica di default (ToS 0)
  - optionalmente per le altre metriche
- I pacchetti IP vengono quindi instradati sulla base del valore contenuto nel campo ToS del loro header

locigno@disi.unitn.it

48

---

---

---

---

---

---

## Il protocollo OSPF

- Il protocollo OSPF utilizza a sua volta 3 protocolli per svolgere le proprie funzionalità
  - Hello Protocol
  - Exchange Protocol
  - Flooding Protocol

locigno@disi.unitn.it

49

---

---

---

---

---

---

## Messaggi OSPF (1)

- I messaggi OSPF sono trasportati direttamente all'interno dei pacchetti IP
  - non viene utilizzato il livello di trasporto
  - nelle reti broadcast viene usato un indirizzo multicast
- Tutti i messaggi OSPF condividono lo stesso header

Version #	Type	Packet length
	Router ID	
	Area ID	
Checksum	Auth Type	
	Authentication	
	Authentication	

locigno@disi.unitn.it

50

---

---

---

---

---

---

## Messaggi OSPF (2)

- Version # = 2
- Type: indica il tipo di messaggio
- Packet Length: numero di byte del messaggio
- Router ID: indirizzo IP del router di riferimento

Version #	Type	Packet length
	Router ID	
	Area ID	
Checksum	Auth Type	
	Authentication	
	Authentication	

locigno@disi.unitn.it

51

---

---

---

---

---

---

## Messaggi OSPF (3)

- Area ID: identificativo dell'area
  - 0 per la Backbone area
- Auth Type: tipo di autenticazione
  - 0 no autenticazione, 1 autenticazione con passwd
- Authentication: password

Version #	Type	Packet length

Authentication		

locigno@disi.unitn.it

52

---

---

---

---

---

---

## Il protocollo Hello

- Funzioni:
  - verificare l'operatività dei link
  - elezione del *designated router* (e relativo elemento di backup)
- Messaggi:
  - Hello

Common header (type = 1, hello)		
Network mask		
Hello interval	Options	Priority
Dead interval		
Designated router		
Backup Designated router		
Neighbor		

locigno@disi.unitn.it

53

---

---

---

---

---

---

## Hello Protocol: formato pacchetto (1)

- Network mask: maschera della sottorete cui appartiene l'interfaccia
- Hello interval: intervallo temporale di separazione tra due messaggi di Hello

Common header (type = 1, hello)		
Network mask		
Hello interval	Options	Priority
Dead interval		
Designated router		
Backup Designated router		
Neighbor		

locigno@disi.unitn.it

54

---

---

---

---

---

---

## Hello Protocol: formato pacchetto (2)

- Designated router: indirizzo IP del designated router
  - 0 se non è stato ancora eletto
- Backup designated router: indirizzo IP del backup designated router

Common header (type = 1, hello)		
Network mask		
Hello interval	Options	Priority
Dead interval		
Designated router		
Backup Designated router		
Neighbor		

locigno@disi.unitn.it

55

---

---

---

---

---

---

---

## Hello Protocol: formato pacchetto (3)

- Neighbor: lista di nodi adiacenti da cui ha ricevuto un messaggio di Hello negli ultimi **dead interval** secondi

Common header (type = 1, hello)		
Network mask		
Hello interval	Options	Priority
Dead interval		
Designated router		
Backup Designated router		
Neighbor		

locigno@disi.unitn.it

56

---

---

---

---

---

---

---

## Il protocollo Exchange

- Funzioni:
  - sincronizzazione dei database link state (bring up adjacencies) tra due router che hanno appena verificato l'operatività bidirezionale del link che li connette
  - protocollo client-server
  - messaggi:
    - Database Description Packets
    - Link State Request
    - Link State Update
  - N.B. il messaggio Link State Update viene distribuito secondo le politiche del protocollo di Flooding

locigno@disi.unitn.it

57

---

---

---

---

---

---

---

---

## Exchange Protocol: messaggi (1)

- Database Description

Common header (type = 2, db description)			
0	0	Options	0
DD sequence number			
Link State Type			
Link State ID			
Advertising router			
Link State Sequence Number			
Link State Checksum	Link State Age		

locigno@disi.unitn.it

58

---

---

---

---

---

---

---

## Exchange Protocol: messaggi (2)

- Link State Request

Common header (type = 3, link state request)			
Link State Type			
Link State ID			
Advertising router			

- Link state Update

Common header (type = 4, link state update)			
Number of link state advertisement			
Link state advertisement #1			
Link state advertisement #2			

locigno@disi.unitn.it

59

---

---

---

---

---

---

---

## Il protocollo di Flooding

- Funzioni:

- aggiornare il database link state dell'autonomous system a seguito del cambiamento di stato di un link

- Messaggi:
  - Link State Update

Common header (type = 4, link state update)			
Number of link state advertisement			
Link state advertisement #1			
Link state advertisement #2			

locigno@disi.unitn.it

60
