

Logics for Data and Knowledge Representation

First Order Logics (FOL)

Originally by Alessandro Agostini and Fausto Giunchiglia
Modified by Fausto Giunchiglia, Rui Zhang and Vincenzo Maltese

Outline

- Introduction
- Syntax
- Semantics
- Reasoning Services

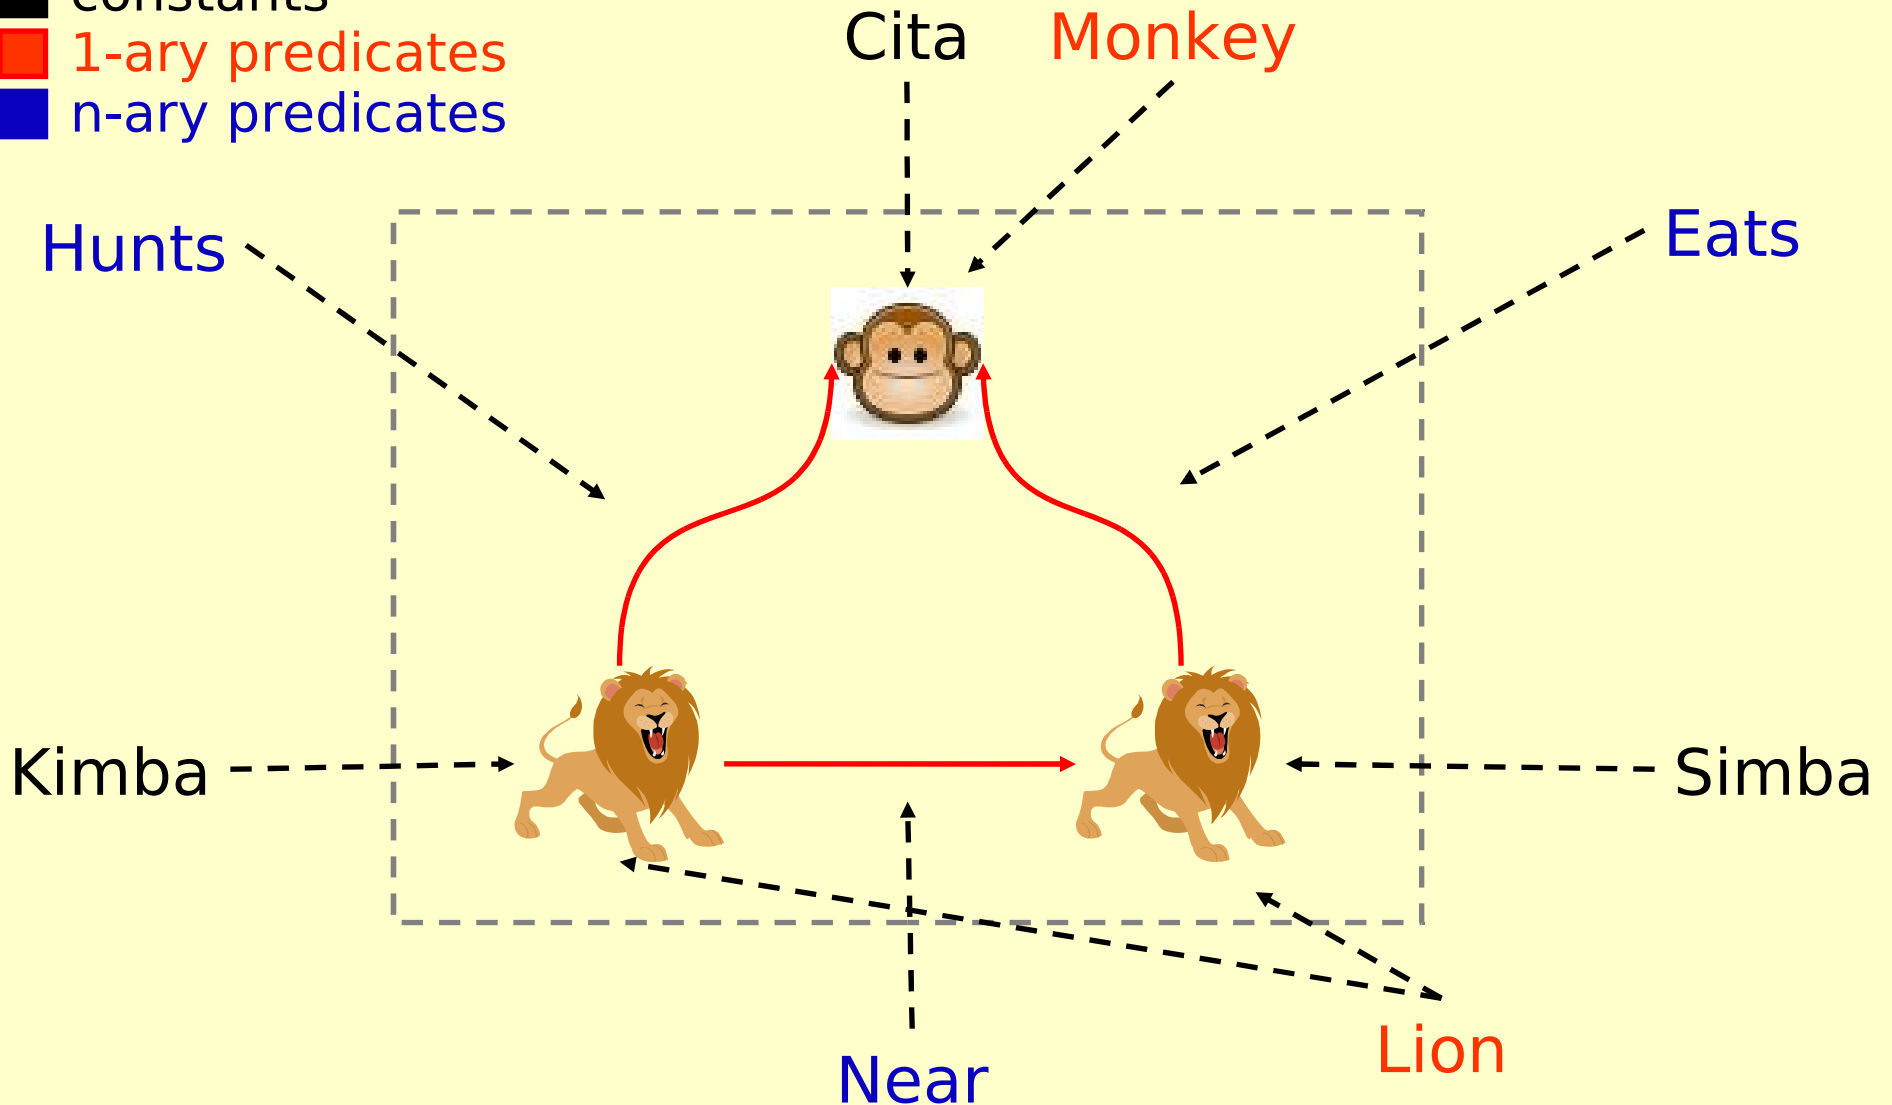

The need for greater expressive power

- ❑ We need FOL for a greater expressive power. In FOL we have:
 - ❑ **constants/individuals** (e.g. 2)
 - ❑ **variables** (e.g. x)
 - ❑ **Unary predicates** (e.g. Man)
 - ❑ **N-ary predicates** (eg. Near)
 - ❑ **functions** (e.g. Sum, Exp)
 - ❑ **quantifiers** (\forall , \exists)
 - ❑ **equality symbol =** (optional)

- ❑ **n-ary relations** express objects in D^n **Near(A,B)**
- ❑ **Functions** return a value of the domain, $D^n \rightarrow D$ **Multiply(x,y)**
- ❑ **Universal quantification** $\forall x \text{ Man}(x) \rightarrow \text{Mortal}(x)$
- ❑ **Existential quantification** $\exists x (\text{Dog}(x) \wedge \text{Black}(x))$

Example of what we can express in FOL

- constants
- 1-ary predicates
- n-ary predicates

Alphabet of symbols

- **Variables** x_1, x_2, \dots, y, z
 - **Constants** a_1, a_2, \dots, b, c
 - **Predicate symbols** $A_1^1, A_2^1, \dots, A_m^n$
 - **Function symbols** $f_1^1, f_2^1, \dots, f_m^n$
 - **Logical symbols** $\wedge, \vee, \neg, \rightarrow, \forall, \exists$
 - **Auxiliary symbols** $()$
- Indexes on top are used to denote the number of arguments, called **arity**, in predicates and functions.
 - Indexes on the bottom are used to disambiguate between symbols having the same name.
 - Predicates of arity =1 correspond to **properties or concepts**

Terms and well formed formulas

- **Terms** can be defined using the following BNF grammar:
 - $\langle \text{term} \rangle ::= \langle \text{variable} \rangle \mid \langle \text{constant} \rangle \mid \langle \text{function sym} \rangle (\langle \text{term} \rangle \{, \langle \text{term} \rangle \}^*)$
- A term is a **closed term** iff it does not contain variables, e.g. $\text{Sum}(2,3)$
- **Well formed formulas** (wff) can be defined as follows:
 - $\langle \text{atomic formula} \rangle ::= \langle \text{predicate sym} \rangle (\langle \text{term} \rangle \{, \langle \text{term} \rangle \}^*) \mid$
 $\langle \text{term} \rangle = \langle \text{term} \rangle$
 - $\langle \text{wff} \rangle ::= \langle \text{atomic formula} \rangle \mid \neg \langle \text{wff} \rangle \mid \langle \text{wff} \rangle \wedge \langle \text{wff} \rangle \mid \langle \text{wff} \rangle \vee \langle \text{wff} \rangle \mid$
 $\langle \text{wff} \rangle \rightarrow \langle \text{wff} \rangle \mid \forall \langle \text{variable} \rangle \langle \text{wff} \rangle \mid \exists \langle \text{variable} \rangle \langle \text{wff} \rangle$

NOTE: $\langle \text{term} \rangle = \langle \text{term} \rangle$ is optional. If it is included, we have a **FO language with equality**.

NOTE: We can also write $\exists x.P(x)$ or $\exists x:P(x)$ as notation (with ‘.’ or “:”)

Scope and index of logical operators

Given two wff α and β

□ Unary operators

In $\neg\alpha$, $\forall x\alpha$ and $\exists x\alpha$,

α is the scope and x is the index of the operator

□ Binary operators

In $\alpha \wedge \beta$, $\alpha \vee \beta$ and $\alpha \rightarrow \beta$,

α and β are the scope of the operator

NOTE: in the formula $\forall x_1 A(x_2)$, x_1 is the index but x_1 is not in the scope, therefore the formula can be simplified to $A(x_2)$.

Free and bound variables

- ❑ A variable x is bound in a formula γ if it is $\gamma = \forall x \alpha(x)$ or $\exists x \alpha(x)$ that is x is both in the index and in the scope of the operator.
- ❑ A variable is free otherwise.
- ❑ A formula with no free variables is said to be a sentence or closed formula.
- ❑ A FO theory is any set of FO-sentences.

NOTE: we can substitute the bound variables without changing the meaning of the formula, while it is in general not true for free variables.

Interpretation function

- An interpretation I for a FO language L over a domain D is a function such that:
 - $I(a_i) = a_i$ for each constant a_i
 - $I(A^n) \subseteq D^n$ for each predicate A of arity n
 - $I(f^n)$ is a function $f: D^n \rightarrow D \subseteq D^{n+1}$ for each function f of arity n

Assignment

- An assignment for the variables $\{x_1, \dots, x_n\}$ of a FO language L over a domain D is a mapping function a :
 $\{x_1, \dots, x_n\} \rightarrow D$

$$a(x_i) = d_i \in D$$

NOTE: In countable domains (finite and enumerable) the elements of the domain D are given in an ordered sequence $\langle d_1, \dots, d_n \rangle$ such that the assignment of the variables x_i follows the sequence.

NOTE: the assignment a can be defined on free variables only.

Interpretation over an assignment a

- An interpretation I_a for a FO language L over an assignment a and a domain D is an extended interpretation where:
 - $I_a(x) = a(x)$ for each variable x
 - $I_a(c) = I(c)$ for each constant c
 - $I_a(f^n(t_1, \dots, t_n)) = I(f^n)(I_a(t_1), \dots, I_a(t_n))$ for each function f of arity n

NOTE: I_a is defined on terms only

Satisfaction relation

- We are now ready to provide the notion of **satisfaction relation**:

$$M \models \gamma [a]$$

(to be read: M satisfies γ under a or γ is true in M under a)

where:

- M is an interpretation function I over D
 M is a mathematical structure $\langle D, I \rangle$
- a is an assignment $\{x_1, \dots, x_n\} \rightarrow D$
- γ is a FO-formula

NOTE: if γ is a sentence with no free variables, we can simply write: $M \models \gamma$ (without the assignment a)

Satisfaction relation for well formed formulas

□ γ atomic formula:

□ $\gamma: t_1 = t_2$ $M \models (t_1 = t_2)[a]$ iff $I_a(t_1) = I_a(t_2)$

□ $\gamma: A^n(t_1, \dots, t_n)$ $M \models A^n(t_1, \dots, t_n)[a]$ iff $(I_a(t_1), \dots, I_a(t_n)) \in I(A^n)$

Satisfaction relation for well formed formulas

□ γ well formed formula:

- $\gamma: \neg \alpha$ $M \models \neg \alpha [a]$ iff $M \not\models \alpha [a]$
- $\gamma: \alpha \wedge \beta$ $M \models \alpha \wedge \beta [a]$ iff $M \models \alpha [a]$ and $M \models \beta [a]$
- $\gamma: \alpha \vee \beta$ $M \models \alpha \vee \beta [a]$ iff $M \models \alpha [a]$ or $M \models \beta [a]$
- $\gamma: \alpha \rightarrow \beta$ $M \models \alpha \rightarrow \beta [a]$ iff $M \not\models \alpha [a]$ or $M \models \beta [a]$

- $\gamma: \forall x_i \alpha$ $M \models \forall x_i \alpha [a]$ iff $M \models \alpha [s]$ for all assignments
 $s = \langle d_1, \dots, d'_i, \dots, d_n \rangle$ where s varies from a only
 for the i -th element (s is called an **i -th variant of a**)

- $\gamma: \exists x_i \alpha$ $M \models \exists x_i \alpha [a]$ iff $M \models \alpha [s]$ for some assignment
 $s = \langle d_1, \dots, d'_i, \dots, d_n \rangle$ i -th variant of a

Satisfaction relation for a set of formulas

- We say that a formula γ is true (w.r.t. an interpretation I) iff every assignment $s = \langle d_1, \dots, d_n \rangle$ satisfies γ , i.e. $M \models \gamma [s]$ for all s .

NOTE: under this definition, a formula γ might be neither true nor false w.r.t. an interpretation I (it depends on the assignment)

- If γ is true under I we say that I is a model for γ .
- Given a set of formulas Γ , M satisfies Γ iff $M \models \gamma$ for all γ in Γ

Satisfiability and Validity

- We say that a formula γ is **satisfiable** iff there is a structure $M = \langle D, I \rangle$ and an assignment a such that $M \models \gamma [a]$
- We say that a set of formulas Γ is **satisfiable** iff there is a structure $M = \langle D, I \rangle$ and an assignment a such that $M \models \gamma [a]$ for all γ in Γ
- We say that a formula γ is **valid** iff it is true for any structure and assignment, in symbols $\models \gamma$
- A set of formulas Γ is **valid** iff all formulas in Γ are valid.

Entailment

- Let be Γ a set of FO- formulas, γ a FO- formula, we say that

$$\Gamma \models \gamma$$

(to be read Γ entails γ)

iff for all the interpretations M and assignments a ,
if $M \models \Gamma [a]$ then $M \models \gamma [a]$.

Reasoning Services: EVAL

Model Checking (EVAL)

Is a FO-formula γ true under a structure $M = \langle D, I \rangle$ and an assignment a ? Check $M \models \gamma [a]$

Satisfiability (SAT)

Given a FO-formula γ , is there any structure $M = \langle D, I \rangle$ and an assignment a such that $M \models \gamma [a]$?

Validity (VAL)

Given a FO-formula γ , is γ true for all the interpretations M and assignments a , i.e. $\models \gamma$?

NOTE: they are decidable in finite domains

How to reason on finite domains

- $\models \forall x P(x) [a]$ $D = \{a, b, c\}$
we have only 3 possible assignments $a(x) = a, a(x) = b, a(x) = c$
we translate in $\models P(a) \wedge P(b) \wedge P(c)$
- $\models \exists x P(x) [a]$ $D = \{a, b, c\}$
we have only 3 possible assignments $a(x) = a, a(x) = b, a(x) = c$
we translate in $\models P(a) \vee P(b) \vee P(c)$
- $\models \forall x \exists y R(x,y) [a]$ $D = \{a, b, c\}$
we have 9 possible assignments, e.g. $a(x) = a, a(y) = b$
we translate in $\models \exists y R(a,y) \wedge \exists y R(b,y) \wedge \exists y R(c,y)$
and then in $\models (R(a,a) \vee R(a,b) \vee R(a,c)) \wedge$
 $(R(b,a) \vee R(b,b) \vee R(b,c)) \wedge$
 $(R(c,a) \vee R(c,b) \vee R(c,c))$
